Abstract

- VIREL is a novel, theoretically grounded probabilistic inference framework for reinforcement learning (RL) that utilises the action-value function in a parametrised form to capture future dynamics of the underlying Markov decision process
- Applying the variational expectation-maximisation algorithm to our framework, we show that the actor-critic algorithm can be reduced to expectation-maximization
- VIREL is a more flexible and mathematically grounded alternative to existing RL-asinference frameworks such as the maximum entropy or pseudo-likelihood approaches

Reinforcement Learning as Inference

- The RL problem is to find an optimal policy $\pi^*(a|s) \in \Pi^* \triangleq \arg \max_{\pi} J^{\pi}$, where $J^{\pi} \triangleq \int Q^{\pi}(h) p_0(s) \pi(a|s) dh$
- RL as inference approaches recast the RL problem as an inference problem in which maximizing a marginal likelihood is equivalent to maximizing the reward function J^{π}
- Existing RL-as-inference frameworks:
- Maximum Entropy RL: no closed-form updates for the parameters of value functions without using approximations
- Pseudo-Likelihood RL: promotes risk-seeking policies

Variational Expectation-Maximization

- In variational inference, we seek to maximize the marginal likelihood, p(x)
- For any valid probability distribution q(h) over h we can rewrite the log-marginal likelihood objective as a difference of two KL divergences,

$$\begin{aligned} \mathcal{L}(x;\omega) &= \int q(h) \log\left(\frac{p(x,h;\omega)}{q(h)}\right) dh - \int q(h) \log\left(\frac{p(h|x;\omega)}{q(h)}\right) dh \\ &= & \text{ELBO}\left(q(h);\omega\right) + \text{KL}(q(h) \parallel p(h|x;\omega)), \end{aligned}$$

where ELBO $(q(h)) \triangleq \int q(h) \log \left(\frac{p(x,h)}{q(h)}\right) dh$ is known as the evidence lower bound

- Variational expectation-maximization:
 - Variational E-Step: $\theta_{n+1} \leftarrow \arg \max_{\alpha} \text{ELBO}(q(h; \theta); \omega_n)$ Variational M-Step: $\omega_{n+1} \leftarrow \arg \max \text{ELBO}(q(h; \theta_{n+1}); \omega)$

VIREL: A Variational Inference Framework for Reinforcement Learning

Matthew Fellows, Anuj Mahajan, Tim G. J. Rudner, Shimon Whiteson

VIREL Framework

• Optimality of reward:

 $p(\mathcal{O}|h;\omega) = \exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{\mathcal{O}} \left(1 - \exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{\mathcal{O}} \left(1 - \exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{\mathcal{O}} \right)^{\mathcal{O}} \left(1 - \exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{\mathcal{O}} \left(1 - \exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{\mathcal{O}} \right)^{\mathcal{O}} \right)^{\mathcal{O}} \left(1 - \exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{\mathcal{O}} \left(1 - \exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{\mathcal{O}} \right)^{\mathcal{O}} \right)^{\mathcal{O}} \left(1 - \exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{\mathcal{O}} \left(1 - \exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{\mathcal{O}} \right)^{\mathcal{O}} \left(1 - \exp\left(\frac{Q^{p_$

• Mean squared Bellman error (MSBE):

$$\beta(\omega) = \mathbb{E}_{h \sim p(h|\mathcal{O};\omega)} \left[\left(Q^{p_{\omega}}(h) \right) \right]$$

- $Q^{p_{\omega}}(h)$ is the target Q-function: the action-value of the policy corresponding to the action-posterior distribution, $p(a|s, \mathcal{O}; \omega)$
- Inference objective:

$$\mathbb{ELBO}(q,\omega) = \frac{\int Q^{p_{\omega}}(h) p_0(s) \pi^q(a|s) dh}{\beta(\omega)} + \mathcal{H}(q(h)) + \mathbb{E}_{h \sim q(h)}[\log(p(h))]$$

$$\exp\left(\frac{Q^{p_{\omega}}(h)}{\beta(\omega)}\right)^{(1-\mathcal{O})}$$

$$\hat{Q}(h;\omega)\Big)^2\Bigg]$$

DEFINITION

Lemma 1 (Characterisation of posterior). *If all optimal policies and corresponding opti*mal Q-functions can be represented exactly by distributions parametrised by ω , then the action-posterior $p(a|s, \mathcal{O}; \omega)$ defines a soft policy with respect to $Q^{p_{\omega}}(h)$ with the temperature given by the residual error $\beta(\omega)$. In the limit $\lim_{\beta(\omega)\to 0} p(a|s, \mathcal{O}; \omega)$ is greedy with respect to $Q^{p_{\omega}}(h)$.

Theorem 1 (Optimal Posterior Distributions as Optimal Policies). For any ω that maximizes $\mathcal{L}(\omega)$, the corresponding policy induced must be optimal, i.e.,

 $\omega^* \in \operatorname{arg\,max} \mathcal{L}(\omega) \implies p(a|s, \mathcal{O}; \omega^*) \in \operatorname{arg\,max} J^{\pi}.$

Variational Actor-Critic Algorithm

Variational E-Step (Actor):

$$\theta_{k+1} \leftarrow \theta_k$$

wi+'

$$\nabla_{\theta} \text{ELBO}\left(\omega_{k},\theta\right) = \nabla_{\theta} \sum_{t=1}^{T-1} \int \hat{Q}(s_{t},a;\omega) \pi^{q}(a|s_{t};\theta) da + \beta(\omega) \nabla_{\theta} \sum_{t=1}^{T-1} \mathcal{H}(\pi^{q}(a|s_{t};\theta)),$$

where we have used a T time step Monte Carlo estimation of the outer expectation with respect to s

Variational M-Step (Critic):

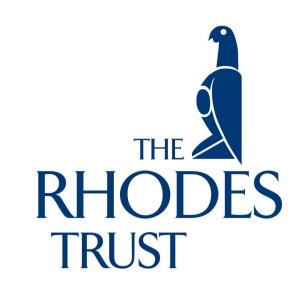

$$\omega_{k+1} \leftarrow \omega_k$$

with

$$\nabla_{\omega} \text{ELBO}\left(\omega, \theta_{k+1}\right) = \mathbb{E}_{h \sim q(h;\theta_{k+1})} \left[\nabla_{\omega} \hat{Q}(h;\omega) \left(\psi(h) - \hat{Q}(h;\omega) \right) \right].$$

- inference methods
- methods
- dimensional domains (such as MuJoCo humanoid)

Main Results

 $\mathcal{P}_k + \alpha_{\text{actor}} \nabla_{\theta} \text{ELBO}\left(\omega_k, \theta\right),$

 $+ \alpha_{\text{critic}} \nabla_{\omega} \text{ELBO}(\omega, \theta_{k+1}),$

Our choice of estimate $\psi(h_0)$ thus determines the form of policy evaluation. We can recover, for example, recover Q-learning by letting $\psi(h) = r(h) + \gamma \max'_a Q(h'; \omega_k)$

Conclusions

• Owing to its generality, our framework is amenable by a wide range of variational

• Our framework does not suffer from the same shortcomings as existing RL-as-inference

• An empirical evaluation showed that VIREL outperforms or performs on par with current state-of-the-art RL models, performing particularly well in difficult high-
